

Cloud Storage Migration — Executive Summary

Project: Jays Shop Retail Platform

Date: 27 July 2026

Prepared for: Management

Status: Complete and live.

The migration to Cloudflare R2 storage has been completed and is operating in production. Media uploads have been verified as working, and the associated security remediation is complete. One recommended action remains outstanding, detailed at the end of this summary.

Business outcome

Service reliability for the storefront's product and promotional media has been restored: the previous storage provider had reached its plan limit and begun rejecting requests, which caused promotional imagery to fail to display on the site. Media are now served from a provider with no data-transfer (egress) fees, whereas the previous provider billed for every gigabyte delivered to site visitors — reducing ongoing storage cost as traffic grows. A related data-exposure risk, described below, has also been identified and substantially remediated.

Current state

Item	Detail
Storage provider	Cloudflare R2 (cloud media storage)
Bucket	One production storage container, configured through secure platform settings
Upload method	Administrators upload promotional videos directly from their browser to storage using a temporary, single-use upload link; files no longer route through the application's own server
Verification performed	A promotional video (6.4 MB) was uploaded and confirmed retrievable by site visitors

Issues identified and resolved

Issue	Plain-English description	Status
Upload permission gap	The storage container did not yet permit direct browser uploads from the admin dashboard.	Resolved
Upload validation error	An automatic file-integrity check was being applied incorrectly, causing valid uploads to be rejected.	Resolved
Storage address duplication	A configuration value briefly caused the storage location to be referenced incorrectly. Later confirmed not to be the underlying cause.	Resolved
Root cause — hidden character in a stored credential	An invisible extra character in a stored access credential was silently invalidating every upload request. Correcting the stored value resolved uploads fully.	Resolved

Security

A document containing a live storage credential was inadvertently committed to the project's records. The exposed credential has been rotated and the prior value confirmed invalid. The codebase has separately been cleaned of

hardcoded account passwords, and a full scan of the current codebase confirms no credentials remain present. Copies of the retired values remain in historical version-control records, which cannot be altered retroactively; rotating the affected account's password is the remaining step required to fully close this exposure.

Recommendation

Rotate the password for the admin@jays.shop account.

Owner: Site Administrator. This is the sole outstanding action; all other remediation and migration work described above is complete.

This document contains no credentials, API keys, passwords, tokens, or connection strings. Condensed executive version of the full R2 storage management report (available in docs/out/), which contains full commit references for technical audit purposes.
